AB Protein purification that combines the use of molecular mass exclusion membranes with electrophoresis is particularly powerful as it uses properties inherent to both techniques. The use of membranes allows efficient processing and is easily scaled up, while electrophoresis permits high resolution separation under mild conditions. The Gradiflow apparatus combines these two technologies as it uses polyacrylamide membranes to influence electrokinetic separations. The reflux electrophoresis process consists of a series of cycles incorporating a forward phase and a reverse phase. The forward phase involves collection of a target protein that passes through a separation membrane before trailing proteins in the same solution. The forward phase is repeated following clearance of the membrane in the reverse phase by reversing the current. We have devised a strategy to establish optimal reflux separation parameters, where membranes are chosen for a particular operating range and protein transfer is monitored at different pH values. In addition, forward and reverse phase times are determined during this process. Two examples of the reflux method are described. In the first case, we describe the purification strategy for proteins from a complex mixture which contains proteins of higher electrophoretic mobility than the target protein. This is a two-step procedure, where first proteins of higher mobility than the target protein are removed from the solution by a series of reflux cycles, so that the target protein remains as the leading fraction. In the second step the target protein is collected, as it has become the leading fraction of the remaining proteins. In the second example we report the development of a reflux strategy which allowed a rapid one-step preparative purification of a recombinant protein, expressed in Dictyostelium discoideum. These strategies demonstrate that the Gradiflow is amenable to a wide range of applications, as the protein of interest is not necessarily required to be the leading fraction in solution.

AB Using the patented Gradiflow system in conjunction with newly developed affinity membranes, the suitability of an electrokinetic technique for affinity fractionation was investigated. Blue dextran incorporated into an affinity membrane was used to deplete a solution of horse serum of albumin, with the result that a majority of serum proteins were enriched tenfold relative to albumin. The technique, when fully developed, would offer some advantages over affinity chromatography, since to a degree it is possible to control which components of the sample are presented to the affinity matrix. Furthermore, the technique would extend the capabilities of the already multifunctional Gradiflow system.

AB The Gradiflow is a preparative electrophoresis apparatus, allowing fractionation based on a combination of size and charge of proteins in their native (unreduced) form. The preparative fractionation of two proteins of similar size and isoelectric point is demonstrated using the Gradiflow. A separation membrane of appropriate pore size was chosen and then fractionation was "fine tuned" by selecting an appropriate buffer pH to accentuate charge differences between the proteins of interest. Complete separation of mg quantities of bovine serum albumin and ovalbumin was achieved within 40 min.*

AB Thousands of proteins may be visualized on a two-dimensional (2-D) get, but only hundreds are present at levels sufficient for chemical analysis. Therefore, prefractionation of protein samples prior to 2-D polyacrylamide gel electrophoresis (PAGE) will be important for the investigation of proteins that are present at sub-picogram levels in physiological samples. We describe an approach to prefractionate protein samples prior to 2-D PAGE using the Gradiflow, which is a new (preparative) electrokinetic membrane apparatus designed to fractionate proteins in a number of different ways. We have fractionated human serum under nonreducing conditions using the 'reflux' mode, in which proteins are fractionated according to their relative mobility under controlled electrophoretic conditions, where the current is periodically reversed. We describe how fractionation occurs and present examples of enrichment of specific proteins.

AB Precast gradient gels of short migration length (25 mm) have been developed to provide rapid electrophoretic separation without loss of resolution. These Micrograd gels have been prepared in gel ranges (conventional and unique) to match pore-gradient electrophoresis conditions to proteins/peptides ranging in size from several hundreds to millions. The Hylinx Micrograd gel combines an extreme gel range (6 to 48% polyacrylamide) with a novel crosslinker to provide sieving of polypeptides, and pore-limit electrophoresis of the smallest proteins (e.g. insulin monomer). All gel ranges (such as 3 to 30%) provide zone sharpening in routine analysis of conventional protein mixtures (e.g. serum) within 10 min electrophoresis at 200 to 300 volts. The gels are thin (1 mm) and thus stain quickly, but the gel cassette is of conventional overall width (83 mm), thus fitting many apparatus designs and accommodating 12 samples. The gels are finding valuable use in screening applications, requiring the electrophoretic analysis of many samples, and in cases where a rapid answer is needed, such as monitoring protein purification. The gels have proved particularly useful, in-house, for the latter application in developing Gradipore's new large-scale preparative electrophoresis system, the Gradiflow.

CC 9-16 (Biochemical Methods)

AB The adsorption properties of protein A hollow fiber affinity membrane were studied using human γ-Ig as a model protein. Anti-human chorionic gonadotropin monoclonal antibody was purified from mouse ascites. SDS-polyacrylamide gel electrophoretic anal. showed that the purified antibody has high purity.

AB The application of a medium-free, continuous-flow electrophoretic separation was evaluated for the characterization and purification of rabbit serum proteins and antibody. Electrophoretic sepns. of large vols. of whole antiserum, serum, or fractions which corresponded well to the distribution of serum proteins in agar gel or other types of electrophoresis were obtained. Considerable electrophoretic heterogeneity was observed for the antibody of 2 pooled sera. The electrophoretic method described is a useful addnl. method for the preliminary physicochem. purification of antibody. 23 references.

AB The title method and apparatus, for the continuous separation of a target protein or protein fraction from a protein mixture containing ≥2 proteins at a pH equal to the pI of the target protein, is provided. The apparatus includes ≥1 nonionic, nonelec. conductive porous membrane conduit through which the protein mixture-containing solution is passed. The conduit, of polysulfone, polyether sulfone, polypropylene, or polyvinylidene difluoride, is positioned to serve as a septum between the buffer chambers and is adapted to permit free flow of electrophoretically driven proteins across the diameter of the conduit. The membrane is

impregnated with a hydrogel to decrease its hydraulic permeability. The conduit is subjected to the influence of an elec. field substantially perpendicular to fluid flow through it, resulting in movement of all charged proteins from the conduit lumen. The target protein, which is unaffected by the elec. field when the pH is its pI, is collected from the conduit outlet in substantially purified form. Thus, a polypropylene fiber membrane (0.2 μm pore diameter) was impregnated with 1% (weight/volume) agarose and the dry membrane was wetted 1st in Me2CHOH, then in water. The rewetted membrane was submerged in 1% agarose at .apprx.60° for 16-24 h, then drained of excess hydrogel, cooled, and mounted in the apparatus chamber (schematic diagrams included). Using 0.06 M barbital buffer (pH 8.6) as carrier buffer, the apparatus was used to sep. γ-globulins from a protein mixture also containing cytochrome C and phycocyanin. The presence of γ-globulins inside the membrane and the selective removal of cytochrome C and phycocyanin into the surrounding buffer chambers was confirmed by gel electrophoresis anal.
